Python & C++
FARSCOPE workshops

Bristol Robotics Lab

University of the West of England/University of Bristol

FIRST OF THREE WORKSHOPS

- Introduction to programming in Python and C++
- Software engineering (including things like git)
- o ROS

FIRST OF THREE WORKSHOPS

- Introduction to programming in Python and C++
- o Software engineering (including things like git)
- o ROS
- o At the end: confident computer scientists for robotics
- Mostly hands-on! not lectures

Go to www.menti.com and use the code 60 58 02

Head to robomaze.skadge.org

CURL AND THE TERMINAL

Fire up a terminal window, and try to create a robot:

\$ curl 'https://robomaze.skadge.org/api?move=\["Wall-E","E"\]'

FIRST TASK

Clone the robomaze project and run one simple example:

- \$ git clone https://github.com/severin-lemaignan/robomaze.git
- \$ cd robomaze/scripts
- \$ python random_walk.py Wall-E

Then, modify the script to make sure your robot does not die.

SECOND TASK

Write a clever algorithm to get to the end of the maze!

- Breadth first
- Depth first
- Grassfire
- o Dijkstra's shortest path
- o A*

GRASSFIRE ALGORITHM

```
import queue
3
    0 = aueue.Oueue()
4
    def grassfire(M, goal):
        Q.push(goal)
        M[goal] = 0 # set goal value to 0
        while not Q.empty(): # loop until map filled
9
             a = 0.pop()
             for n in neighbours(a):
                 if not n in M and not is_obstacle(n):
                     Q.push(n)
14
                     M[n] = M[a] + 1
         return M
16
```

Q is a queue data structure, a first-in first-out (fifo) list. The queue keeps track of which locations on the map still need to be visited.

SEARCHING GRAPHS - A*

```
def astar(start, end):
 1
 3
       cost_to = {} # maps nodes to distance to 'start_node'
       cost to[start] = 0
 4
       come_from = {} # needed to reconstruct shortest path
 6
       nodes to visit = \( \( \text{(start.0)} \) \( \text{(node. 'total' cost)} \)
8
       visited_nodes = []
9
       while nodes_to_visit:
         node,_ = pop_best_node(nodes_to_visit)
         for neighbour in neighbours(node):
14
           if cost_to[node] + 1 < cost_to[neighbour]: # new shorter path to v!</pre>
             cost to [neighbour] = cost to [node] + 1
             nodes_to_visit.append((neighbour, cost_to[neighbour] + \
16
                                          heuristic(neighbour. goal)))
             come_from[neighbour] = node
18
19
20
       return come from
```

<u>C</u>++

COMPILING CODE IN C++

```
/*
  * "Hello, World!": A classic.
  */
#include <iostream>
using namespace std;
int main(void)
{
    cout << "Hello, World!" << endl;
    return 0;
}</pre>
```

COMPILING CODE IN C++

```
/*
    * "Hello, World!": A classic.
    */
#include <iostream>
using namespace std;
int main(void)
{
    cout << "Hello, World!" << endl;
    return 0;
}</pre>
```

\$ g++ hello.cpp -ohello

COMPILING CODE IN C++

```
/*
    * "Hello, World!": A classic.
    */
#include <iostream>
using namespace std;
int main(void)
{
    cout << "Hello, World!" << endl;
    return 0;
}</pre>
```

\$ g++ hello.cpp -ohello

\$./hello Hello, World!

COMPILING CODE IN C++: THE MAIN STAGES

- 1. Pre-processing
- 2. Compilation
- 3. Assembly
- 4. Linking

These four steps are transparently performed one after the other by your favourite compiler.

COMPILING CODE IN C++: PRE-PROCESSING

```
/*
    "Hello, World!": A classic.
    */
#include <iostream>
using namespace std;
int main(void)
{
    cout << "Hello, World!" << endl;
    return 0;
}</pre>
```

Pre-processor directives start with

 \rightarrow #include <iostream> is replaced by the content of that file.

movq

call

```
$ g++ -S hello.cpp
  main:
   .I FB1493:
           .cfi_startproc
           pushq
                         %rbp
           .cfi_def_cfa_offset 16
           .cfi_offset 6, -16
                       %rsp, %rbp
           mova
           .cfi_def_cfa_register 6
           leaq
                       .LC0(%rip), %rsi
           leaq
                       _ZSt4cout(%rip), %rdi
           call
                       _ZStlsISt11char_traitsIcEERSt13basic_ostrea
                       %rax, %rdx
           movq
                       _ZSt4endlIcSt11char_traitsIcEERSt13basic_os
           movq
           movq
                       %rax, %rsi
                       %rdx, %rdi
```

7NSolsEPERSos F@PLT

COMPILING CODE IN C++: ASSEMBLY

```
$ g++ -s hello.cpp
$ hexdump a.out
0000000 457f 464c 0102 0001 0000 0000 0000 0000
0000010 0003 003e 0001 0000 07h0 0000 0000
0000020 0040 0000 0000 0000
                 1128 0000 0000 0000
0000030 0000 0000 0040 0038 0009 0040 001b 001a
0000050 0040 0000 0000 0000 0040 0000 0000 0000
0000070 0008 0000 0000 0000 0003 0000 0004 0000
0000090 0238 0000 0000 0000 001c 0000 0000 0000
00000a0 001c 0000 0000 0000 0001
                    0000 0000 0000
00000e0 0000 0020 0000 0000 0001 0000 0006 0000
```

COMPILING CODE IN C++: LINKING

The linker copies (and re-arrange) the machine code of the static dependencies (*static libraries*) into the executable.

That's what the -1 flag is used for:

```
$ g++ cool_app.cpp -ocool_app -lcv_core -lcv_highgui -lcv_videoproc
```

(more about libraries next time)

COMPILED VS NOT COMPILED

Multiple execution models:

o Compiled languages (eg C, C++, Ada...)

COMPILED VS NOT COMPILED

Multiple execution models:

- o Compiled languages (eg C, C++, Ada...)
- Interpreted languages (eg: ...?)

COMPILED VS NOT COMPILED

Multiple execution models:

- Compiled languages (eg C, C++, Ada...)
- Interpreted languages (eg: ...?)
- $\circ \rightarrow$ most 'interpreted languages' are actually 'JITed'

Just-In-Time compilation: the interpreter generates an efficient **intermediate representation** (commonly called **bytecode**) that is executed (and often stored).

Very common execution model: Python, C#, Javascript...

BACK TO ROBOMAZE AND C++

Let's compile a first example:

```
$ cd robomaze/src
```

\$ g++ request.cpp -orequest

```

STRUCTURE OF THE C++ PROGRAM

```
#include <string>
#include <cpprest/http client.h>
using namespace std;
using namespace web::http::client;
int main(int argc, char* argv[])
    // Create http client to send the request.
    http_client client(U("https://robomaze.skadge.org/"));
    // Build request URI and start the request.
    uri_builder builder(U("/api"));
    builder.append_query(U("move"), U("[\"" + string(argv[1]) +"\", \"" + string(argv[2]) + "\"]"));
    http response response = client.request(methods::GET, builder.to string()).get():
    cout << "Received response status code:" << response.status_code() << endl;</pre>
    // extract the JSON response
    if (response.status_code() == 200) {
        auto ison response = response.extract ison(true).get():
        cout << ison response << endl:
        cout << "Was move successful? " << json_response[0] << endl;</pre>
    else {
        cout << "Error!" << endl;
    return 0:
```

THIRD TASK

Path planning in C++, of course!

...hum...

LET'S ORGANISE THE WORK

 \rightarrow Isolate the A* algorithm from the main.

Three templates in src/:

 controller.cpp: our 'main' (that contains the *entry point* of our program)

LET'S ORGANISE THE WORK

 \rightarrow Isolate the A* algorithm from the main.

Three templates in src/:

- controller.cpp: our 'main' (that contains the *entry point* of our program)
- o astar.cpp: the algorithm itself

LET'S ORGANISE THE WORK

 \rightarrow Isolate the A* algorithm from the main.

Three templates in src/:

- controller.cpp: our 'main' (that contains the entry point of our program)
- o astar.cpp: the algorithm itself
- astar.h: the *header* describing what functionalities astar.cpp provides (eg, its *API*)

ASTAR.H

```
#include <memory> // for unique_ptr
#include <tuple>
#include <string>
typedef std::tuple<unsigned int, unsigned int> Position;
const Position START_POS {1, 1};
const Position END_GOAL {98, 98};
struct Node
    std::unique_ptr<Node> parent;
    Position position;
    unsigned int distance_to_start;
    unsigned int total_cost;
};
class AStar
public:
   AStar();
    Position planNextPosition();
    std::string getNextMove();
private:
    Position current position:
};
```

ASTAR.CPP

```
#include <thread> // std::this_thread::sleep_for
#include <chrono> // std::chrono::seconds
#include "astar.h"
using namespace std;
using namespace std::chrono_literals;
AStar::AStar()
    // todo!
Position AStar::planNextPosition()
    // todo!
std::string AStar::getNextMove()
    // todo!
    this_thread::sleep_for(250ms);
    return "S";
```

CONTROLLER.CPP

```
#include <iostream>
#include <string>
#include <cpprest/http_client.h>
#include "astar h"
int main(int argc, char* argv[])
{
    auto astar = AStar();
    string next_move("E");
    while(true) {
        uri_builder builder(U("/api"));
        builder.append_query(U("move"), U("[\"" + string(argv[1]) +"\",\"" + next_move + "\"]"));
        http_response response = client.request(methods::GET, builder.to_string()).get();
       next_move = astar.getNextMove(response);
```

YOUR TURN!

Starting from these templates, implement, compile and run a path finding algorithm in C++
